

SMART CONTRACT AUDIT REPORT

For

Brainaut

Prepared By: Kishan Patel

Prepared For: SOUF

Prepared on: 17/03/2021

Table of Content

- Disclaimer
- Overview of the audit
- Attacks made to the contract
- Good things in smart contract
- Critical vulnerabilities found in the contract
- Medium vulnerabilities found in the contract
- Low severity vulnerabilities found in the contract
- Summary of the audit

• **Disclaimer**

The audit makes no statements or warranties about utility of the code, safety of the code, suitability of the business model, regulatory regime for the business model, or any other statements about fitness of the contracts to purpose, or their bug free status. The audit documentation is for discussion purposes only.

• **Overview of the audit**

The project has 1 file. It contains approx 730 lines of Solidity code. All the functions and state variables are well commented using the natspec documentation, but that does not create any vulnerability.

• **Attacks made to the contract**

In order to check for the security of the contract, we tested several attacks in order to make sure that the contract is secure and follows best practices.

- **Over and under flows**

An overflow happens when the limit of the type variable `uint256`, 2^{256} , is exceeded. What happens is that the value resets to zero instead of incrementing more. On the other hand, an underflow happens when you try to subtract 0 minus a number bigger than 0. For example, if you subtract $0 - 1$ the result will be $= 2^{256}$ instead of -1 . This is quite dangerous.

This contract **does** check for overflows and underflows by using OpenZeppelin's `SafeMath` to mitigate this attack, but all the functions have strong validations, which prevented this attack.

- **Short address attack**

If the token contract has enough amount of tokens and the buy function doesn't check the length of the address of the sender, the Tron's virtual machine will just add zeros to the transaction until the address is complete.

Although this contract **is not vulnerable** to this attack, but there are some point where users can mess themselves due to this (Please see below). It is highly recommended to call functions after checking validity of the address.

- **Visibility & Delegate call**

It is also known as, The Parity Hack, which occurs while misuse of Delegate call.

No such issues found in this smart contract and visibility also properly addressed. There are some places where there is no visibility defined. Smart Contract will assume "Public" visibility if there is no visibility defined. It is good practice to explicitly define the visibility, but again, the contract is not prone to any vulnerability due to this in this case.

- **Reentrancy / TheDAO hack**

Reentrancy occurs in this case: any interaction from a contract (A) with another contract (B) and any transfer of Tron hands over control to that contract (B).

This makes it possible for B to call back into A before this interaction is completed.

Use of “require” function in this smart contract mitigated this vulnerability.

- **Forcing Tron to a contract**

While implementing “selfdestruct” in smart contract, it sends all the tron to the target address. Now, if the target address is a contract address, then the fallback function of target contract does not get called. And thus Hacker can bypass the “Required” conditions. Here, the Smart Contract’s balance has never been used as guard, which mitigated this vulnerability.

- **Good things in smart contract**

- **Good required condition in functions:-**

- Here you are checking that balance of contract is bigger or equal to the amount and checking that token is successfully transferred to recipient address.

```
293 */
294 ▾ function sendValue(address payable recipient, uint256 amount) internal {
295     require(address(this).balance >= amount, "Address: insufficient balance");
296
297     // solhint-disable-next-line avoid-low-level-calls, avoid-call-value
298     (bool success, ) = recipient.call{ value: amount }("");
299     require(success, "Address: unable to send value, recipient may have reverted");
300 }
```

- Here you are checking that contract has more or equal balance as value amount.

```
354 */
355 ▾ function functionCallWithValue(address target, bytes memory data, uint256 value) public {
356     require(address(this).balance >= value, "Address: insufficient balance for function call");
357     return _functionCallWithValue(target, data, value, errorMessage);
358 }
```

- Here you are checking that target address is proper contract address.

```
360 ▾ function _functionCallWithValue(address target, bytes memory data, uint256 weiValue) private {
361     require(isContract(target), "Address: call to non-contract");
362
363     // solhint-disable-next-line avoid-low-level-calls
364     (bool success, bytes memory returndata) = target.call{ value: weiValue }(data);
365     if (success) {
366         if (returndata.length > 0) {
367             (bool success, ) = target.call{ value: weiValue }(data);
368         }
369     }
370 }
```

- Here you are checking that newOwner address value is proper valid address.

```

440 */
441 function transferOwnership(address newOwner) public virtual onlyOwner {
442     require(newOwner != address(0), "Ownable: new owner is the zero address");
443     emit OwnershipTransferred(_owner, newOwner);
444     _owner = newOwner;
445 }

```

- Here you are checking that deliver address should not be called by the Excluded address.

```

544
545 function deliver(uint256 tAmount) public {
546     address sender = _msgSender();
547     require(!_isExcluded[sender], "Excluded addresses cannot call this function");
548     (uint256 rAmount, uint256 rTotal, uint256 currentRate) = _getValues(tAmount);
549     _deliver(tAmount, sender, rAmount);
550 }

```

- Here you are checking that tAmount value should be less than or equal to the _tTotal amount (Total token value).

```

553
554 function reflectionFromToken(uint256 tAmount, bool deductTransferFee) public {
555     require(tAmount <= _tTotal, "Amount must be less than supply");
556     if (!deductTransferFee) {
557         (uint256 rAmount, uint256 rTotal, uint256 currentRate) = _getValues(tAmount);
558         return rAmount;
559     }
560     (uint256 rAmount, uint256 rTotal, uint256 currentRate) = _getValues(tAmount);
561     return rAmount;
562 }

```

- Here you are checking that rAmount value should be less than or equal to the _rTotal amount (Total reflections value).

```

565 function tokenFromReflection(uint256 rAmount) public view returns(uint256) {
566     require(rAmount <= _rTotal, "Amount must be less than total reflections");
567     uint256 currentRate = _getRate();
568     return rAmount.div(currentRate);
569 }

```

- Here you are checking that account address not already excluded from reward.

```

570
571 function excludeAccount(address account) external onlyOwner() {
572     require(account != 0x7a250d5630B4cF539739dF2C5dAcb4c659F2488D, "We can not exclude the account");
573     require(!_isExcluded[account], "Account is already excluded");
574     if (_rOwned[account] > 0) {
575         (uint256 rAmount, uint256 rTotal, uint256 currentRate) = _getValues(_rOwned[account]);
576         _rOwned[account] = 0;
577         _rTotal -= rAmount;
578         _tTotal -= rAmount;
579     }
580     _isExcluded[account] = true;
581 }

```

- Here you are checking that account address not already included for reward.

```

581 function includeAccount(address account) external onlyOwner() {
582     require(!_isExcluded[account], "Account is already excluded");
583     for (uint256 i = 0; i < _excluded.length; i++) {
584         if (_excluded[i] == account) {
585             _isExcluded[i] = false;
586             _rOwned[account] = _rOwned[i];
587             _rTotal += _rOwned[account];
588             _tTotal += _rOwned[account];
589             _excluded[i] = 0;
590         }
591     }
592 }

```

- Here you are checking that owner and spender address values are proper addresses.

```
593  
594 ▾ function _approve(address owner, address spender, uint256 amount) private {  
595     require(owner != address(0), "BEP20: approve from the zero address");  
596     require(spender != address(0), "BEP20: approve to the zero address");  
597
```

- Here you are checking that addresses values of sender and recipient are proper, amount should be bigger than 0.

```
601  
602 ▾ function _transfer(address sender, address recipient, uint256 amount) private  
603     require(sender != address(0), "BEP20: transfer from the zero address");  
604     require(recipient != address(0), "BEP20: transfer to the zero address");  
605     require(amount > 0, "Transfer amount must be greater than zero");  
606
```

- **Critical vulnerabilities found in the contract**

=> No Critical vulnerabilities found

- **Medium vulnerabilities found in the contract**

=> No Medium vulnerabilities found

- **Low severity vulnerabilities found**

- **7.1: Short address attack:-**

- => This is not big issue in solidity, because now a days is increased In the new solidity version. But it is good practice to Check for the short address.
 - => After updating the version of solidity it's not mandatory.
 - => In all functions you are not checking the value of Address parameter here I am showing only some functions.

- ✚ **Function:- isContract ('account')**

```
266 //
267 function isContract(address account) internal view returns (bool) {
268     // According to EIP-1052, 0x0 is the value returned for not-yet created accounts
269     // and 0xc5d2460186f7233c927e7db2dcc703c0e500b653ca82273b7bfad8045d85a470
270     // for accounts without code, i.e. `keccak256('')`
271     bytes32 codehash;
```

- It's necessary to check the address value of "account". Because here you are passing whatever variable comes in "account" address from outside.

- ✚ **Function:- excludeFromReward, includeInReward ('account')**

```
571 function excludeAccount(address account) external onlyOwner() {
572     require(account != 0x7a250d5630B4cF539739dF2C5dAcb4c659F2488D, 'We can not
573     require(!_isExcluded[account], "Account is already excluded");
574     if(_rOwned[account] > 0) {
575         _tOwned[account] = tokenFromReflection(_rOwned[account]);
```

```
581 function includeAccount(address account) external onlyOwner() {
582     require(!_isExcluded[account], "Account is already excluded");
583     for (uint256 i = 0; i < _excluded.length; i++) {
584         if (_excluded[i] == account) {
585             _excluded[i] = _excluded[_excluded.length - 1];
586             _tOwned[account] = 0;
587             _rOwned[account] = 0;
```

- It's necessary to check the address value of "account". Because here you are passing whatever variable comes in "account" address from outside.

Function: - `_transferBothExcluded` ('sender', 'recipient')

```
655 function _transferBothExcluded(address sender, address recipient, uint256 tAmount)
656     uint256 currentRate = _getRate();
657     (uint256 rAmount, uint256 rTransferAmount, uint256 rFee, uint256 tTransferAmount) =
658     _tOwned[sender] = _tOwned[sender].sub(tAmount);
659     _tOwned[recipient] = _tOwned[recipient].add(tTransferAmount);
660     _rOwned[sender] = _rOwned[sender].sub(rAmount);
661     _rOwned[recipient] = _rOwned[recipient].add(rTransferAmount);
```

- It's necessary to check the addresses value of "sender", "recipient". Because here you are passing whatever variable comes in "sender", "recipient" addresses from outside.

Function: - `_transferStandard`, `_transferToExcluded`, `_transferFromExcluded` ('sender', 'recipient')

```
622
623 function _transferStandard(address sender, address recipient, uint256 tAmount)
624     uint256 currentRate = _getRate();
625     (uint256 rAmount, uint256 rTransferAmount, uint256 rFee, uint256 tTransferAmount) =
626     _tOwned[sender] = _tOwned[sender].sub(tAmount);
627     _tOwned[recipient] = _tOwned[recipient].add(tTransferAmount);
628     _rOwned[sender] = _rOwned[sender].sub(rAmount);
629     _rOwned[recipient] = _rOwned[recipient].add(rTransferAmount);
```

```
633 function _transferToExcluded(address sender, address recipient, uint256 tAmount)
634     uint256 currentRate = _getRate();
635     (uint256 rAmount, uint256 rTransferAmount, uint256 rFee, uint256 tTransferAmount) =
636     _rOwned[sender] = _rOwned[sender].sub(rAmount);
637     _tOwned[recipient] = _tOwned[recipient].add(tTransferAmount);
638     _rOwned[recipient] = _rOwned[recipient].add(rTransferAmount);
639     _tOwned[sender] = _tOwned[sender].add(tAmount);
```

```
643
644 function _transferFromExcluded(address sender, address recipient, uint256 tAmount)
645     uint256 currentRate = _getRate();
646     (uint256 rAmount, uint256 rTransferAmount, uint256 rFee, uint256 tTransferAmount) =
647     _tOwned[sender] = _tOwned[sender].sub(tAmount);
648     _rOwned[sender] = _rOwned[sender].sub(rAmount);
649     _rOwned[recipient] = _rOwned[recipient].add(rTransferAmount);
```

- It's necessary to check the addresses value of "sender", "recipient". Because here you are passing whatever variable comes in "sender", "recipient" addresses from outside.

○ 7.2: Compiler version is not fixed:-

=> In this file you have put “pragma solidity ^0.6.0;” which is not a good way to define compiler version.

=> Solidity source files indicate the versions of the compiler they can be compiled with. Pragma solidity >=^0.6.0; // bad: compiles 0.6.0 and above
pragma solidity 0.6.0; //good: compiles 0.6.0 only

=> If you put(>=) symbol then you are able to get compiler version 0.6.0 and above. But if you don't use(^/>=) symbol then you are able to use only 0.6.0 version. And if there are some changes come in the compiler and you use the old version then some issues may come at deploy time.

=> Use latest version of solidity.

○ 7.3: Approve given more allowance:-

=> I have found that in your approve function user can give more allowance to user beyond their balance..

=> It is necessary to check that user can give allowance less or equal to their amount.

=> There is no validation about user balance.

✚ Function: - approve

```
593  
594 ▾ function _approve(address owner, address spender, uint256 amount) private {  
595     require(owner != address(0), "BEP20: approve from the zero address");  
596     require(spender != address(0), "BEP20: approve to the zero address");  
597  
598     _allowances[owner][spender] = amount;  
599     _balances[owner] -= amount;  
600     _balances[spender] += amount;  
601     emit Approval(owner, spender, amount);  
602 }
```

- Here you can check you have more allowance than balance.

• Summary of the Audit

Overall the code is well and performs well.

Please try to check the address and value of token externally before sending to the solidity code.

Our final recommendation would be to pay more attention to the visibility of the functions , hardcoded address and mapping since it's quite important to define who's supposed to executed the functions and to follow best practices regarding the use of assert, require etc. (which you are doing ;)).

- **Good Point:** Address validation and value validation is done properly.
- **Suggestions:** Please add address validations at some place and also try to use static solidity version, check amount in approve function and I found some place you forgot use safeMath please do it if possible.
